Abstract: When the light photons bounce off a moving mirror, they react with its atoms to be reflected, consequently, the photons change their velocity vector after each impact depending on the velocity vector of the mirror and thus of the atom. The Michelson-Morley experiment was the event that changed the modern science about "the light" by leading to Lorentz and Einstein's theories about time. I made the formulas of the Michelson-Morley experiment by considering the effects of the reflection on the light and the rate (percentage) of fringe shift calculated by the formulas which I demonstrated is perfectly null. As a result, not all physics must be wrong, but only a principle that Einstein and Lorentz stated by fixing the light speed for all observers, which makes us study light in a very difficult way. The formulas demonstrated in this work allow us to study the light as a normal wave and to understand easily all the other light effects without being obliged to use any relativity of the time.

Keywords: Michelson, Morley, light photon, interferometry, mirror, reflection, absorption, emission, null result, reference frame, speed of light, relativity.

1. Introduction

The speed of light has been calculated by maxwell after fixing the electric and magnetic characteristics of the source and of the empty space [1-3]. However, the special relativity considers that the speed of light can only be constant for all observers thanks to the Michelson-Morley experiment [4,7]. It is a theory that has been tested by Kennedy-Thorndike experiment, Ives-Stilwell experiment and many others [8,11]. This theory is also used when dealing with moving light clocks [12,13] and when performing experiments by using lattice clocks [14,15].

Many works still try to present this theory as a correct theory by daring to curve theoretically the space time [16,18] while other rational thinkers stay aware that our space is obviously the Euclidean space and they prove it by their realistic physics works [19,20].

Some researchers refuse both the special relativity and the general relativity and try to disprove their mathematical tools [21] or to prove that the luminiferous aether exists [22,23] or that the relativistic demonstrations can be replaced by easy Newtonian demonstrations [24].

The steps explained in this work when dealing with the light reflection give correct answers and should help to avoid the complicated relativity of time especially in Michelson’s interferometer. In this work, we will prove formulas that predict the null result of Michelson-Morley experiment.

Since we are verifying the experiment results of Michelson-Morley, we are free to change the light velocity vector when it is reflected.

We consider that \( T_1 \) and \( T_2 \) are the times needed by the two half beams to reach the captor starting from the source, and that the splitter doesn’t influence the light when it passes without any deviation through it, otherwise we will have to use compensating plates to correct that.

When a light photon bounces off a moving mirror, it reacts with one of the mirror’s atoms to be reflected through the absorption then the emission. Consequently, the photon gets also an additional velocity vector. It is the velocity vector of the atom during the emission and thus of the mirror.

This phenomenon is similar to a ping pong ball bouncing without friction inside a box that is moving sideways. In this case the ping pong ball gets the box velocity as a sideways component of its velocity vector after it bounces and thus the ball seems to accompany the box in its movement.

In this work, \( \vec{V} \) is the velocity vector of the mirrors and \( c_1 \) is the speed of the light directly after the source. We can consider that: \( c_1 = c \) if the source of the light is fixed during the experiment, where
C is the famous speed constant of the light. And we can consider that: $C_1 = C + V$ if the source of the light moves during the experiment with the velocity $V$. However, the detector (interferometry) is considered always fixed during the experiment.

2. The proposed approach

The figure 1 describes the paths taken by the light beams in Michelson-Morley experiment. In this figure we considered arbitrarily that $\alpha = \beta$ but $\gamma$ different. Also $\tau_2$ and $\tau_3$ are arbitrarily considered different until this work makes the investigation.

The half beam 1 is the one reflected from the mirror 1 and the half beam 2 is the one reflected from the mirror 2.

For half beam 1:
We can prove that:

$$T_1 = 2 \times \left( \frac{L}{C_1} + \frac{V \times t_1}{C_1} \right) + \frac{L}{C_2} - \frac{V \times t_2}{C_2} + \frac{L}{C \sin(\gamma)}$$

(1)

(each term is explained down)

By considering that:

$$C_1 \times t_1 = L + V \times t_1 \Rightarrow t_1 = \frac{L}{C_1 - V}$$

(2)

where $t_1 = \tau_1$.

$C_2$ is the speed of the light returning after being reflected from the mirror 1.

During the reflection operation of the light, the speed of the light photon absorption by the reacting atom of the mirror is $C_1 - V$. Consequently, the photon will be emitted with the same speed (same energy at the absorption) relatively to the reacting atom along the same axis $i$. However, since the atom is moving during the emission with a speed $V \times i$ then: $C_2 = C_1 - 2 \times V$

(3)

By considering also that:

$$C_2 \times t_2 = L - V \times t_2 \text{hence: } t_2 = \frac{L}{C_2 + V} = \frac{L}{C_1 - V}$$

(4)

where: $t_2 = \tau_2 - 2 \times \tau_1$

And that $C_3$ is the speed of light after being reflected from the splitter and before reaching the detector.
The speed of the light photon absorption by the reacting atom of the splitter is: \( C_2 + V = C_1 - V \). Consequently, the photon will be emitted perpendicularly along the axis \( \vec{j} \) with the same speed (same energy at the absorption) relatively to the reacting atom. However, since the reacting atom moves during the emission along the axis \( \vec{i} \) with the speed \( V \), then \( V \times \vec{i} \) will be in this case a component of the emitted photon velocity vector. In the end, the velocity vector will become:

\[
\vec{C}_3 = V \times \vec{i} - (C_1 - V) \times \vec{j}
\]

Hence: \( C_3 = \sqrt{(C_1 - V)^2 + V^2} \) (5)

And \( \cos(\gamma) = \frac{V}{\sqrt{(C_1 - V)^2 + V^2}} \) (6)

\( \sin(\gamma) = \frac{\sqrt{(C_1 - V)^2 + V^2} - (C_1 - V)}{V} \) (7)

And by considering that \( t_3 \) is the time needed by the light to reach the detector after being reflected from the splitter, we have: \( |\sin(\gamma)| = \frac{L}{c_3 \times t_3} \Rightarrow t_3 = \frac{L}{c_3 \times |\sin(\gamma)|} = \frac{L}{c_1 - V} \) (9)

We deduce that:

\[
T_1 = 2 \times \left( \frac{L}{c_1} + \frac{V \times L}{c_1 \times (C_1 - V)} + \frac{L}{c_1 - 2 \times V} - \frac{V \times L}{(C_1 - 2 \times V) \times (C_1 - V)} + \frac{L}{c_1 - V} \times \left( 1 + \frac{2 \times V}{c_1} - \frac{V}{c_1 - 2 \times V} \right) + \frac{V \times L}{c_1 - 2 \times V} \right)
\]

\[
T_1 = \frac{L}{c_1 - 2 \times V} + \frac{2 \times L}{c_1}
\]

For half beam 2:

By following the same steps, we can prove that:

\[
T_2 = \frac{L}{c_1} + \frac{V \times t_1}{c_1} + \frac{L}{c_1 \times |\sin(\alpha)|} + \frac{2 \times L}{c_1 \times |\sin(\beta)|}
\]

\[
(\text{each term is explained down})
\]

By considering that:

\( C'_2 \) is the speed of the light after being reflected from the splitter and before reaching the mirror 2.

Consequently: \( \vec{C}'_2 = V \times \vec{i} + (C_1 - V) \times \vec{j} \) (12)

(similar to the case of \( C_3 \) with half beam 1)

Hence \( \vec{C}'_2 = \sqrt{(C_1 - V)^2 + V^2} \)

\( \sin(\alpha) = \frac{\sqrt{(C_1 - V)^2 + V^2}}{V} \) (14)

\( \cos(\alpha) = \frac{\sqrt{(C_1 - V)^2 + V^2} + (C_1 - V)}{V} \) (15)

And also by considering that:

\( C'_3 \) is the speed of the light after being reflected from the mirror 2 and before reaching the captor.

The speed of the light photon at the absorption is \( \vec{C}'_3 = V \times \vec{i} = (C_1 - V) \times \vec{j} \). Consequently, the photon will be emitted with the same speed (same energy at the absorption) relatively to the reacting atom. However, since the reacting atom moves during the emission along the axis \( \vec{i} \) with the speed \( V \), then: \( \vec{C}'_3 = V \times \vec{i} - (C_1 - V) \times \vec{j} \) (16)

Hence \( C'_3 = \sqrt{(C_1 - V)^2 + V^2} \) (17)

\( \sin(\beta) = \frac{\sqrt{(C_1 - V)^2 + V^2} - (C_1 - V)}{V} \) (18)

\( \cos(\beta) = \frac{\sqrt{(C_1 - V)^2 + V^2} - (C_1 - V)}{V} \) (19)

we deduce that:

\[
T_2 = \frac{L}{c_1} + \frac{V \times L}{c_1 \times (C_1 - V)} + \frac{L}{c_1 - V} + \frac{2 \times L}{c_1 - V} \times \left( 3 + \frac{V}{c_1} \right) + \frac{L}{c_1}
\]

\[
T_2 = \frac{L}{c_1 - V} \times \left( 3 - \frac{V}{c_1} \right) + \frac{V}{c_1 - 2 \times V} - \frac{L}{c_1} - \frac{L}{c_1 - 2 \times V} = 0
\]

Finally:

\[
T_2 - T_1 = \frac{L}{c_1 - V} \times \left( 2 - \frac{V}{c_1} + \frac{V}{c_1 - 2 \times V} \right) - \frac{L}{c_1} - \frac{L}{c_1 - 2 \times V} = 0
\]
We proved above that: $|\alpha| = |\beta|$  \hspace{1cm} (22)
and thus the half beam 2 hits the mirror 2 at:
\[ \tau_{12} = \frac{t_2 - t_1}{2} + \tau_1 \]  \hspace{1cm} (23)
We proved also that: $|\gamma| = |\alpha|$  \hspace{1cm} (24)
and thus the two half beams hit the splitter at the same time $\tau_3 = \tau_2$  \hspace{1cm} (25)
Hence they become parallel before reaching the detector at exactly the same time.

3. Conclusion

The result is made by considering that the speed of light changes by the changing reference frames since this work tests the results of Michelson-Morley experiment and doesn’t consider that Einstein’s conclusion about the luminiferous aether is correct. The rate (percentage) of fringe shift by the formulas demonstrated above is null and thus it confirms theoretically that the result of Michelson-Morley experiment is perfectly null. However, we can’t conclude that the luminiferous aether doesn’t exist like Einstein said or that the speed of the light doesn’t change by a changing reference frame.
